

API Data Flow

Data from Client

The `@JsonProperty` annotation says “send `pswd` as `password` in the JSON.”

```
public class RegistrationInfo {  
    private int userId;  
    private String userName;  
    @JsonProperty("password")  
    private String pswd;  
  
    // getters omitted  
  
    public void setUserId(int userId) {  
        this.userId = userId;  
    }  
  
    public void setUsername(String userName) {  
        this.userName = userName;  
    }  
  
    public void setPswd(String pswd) {  
        this.pswd = pswd;  
    }  
}
```

```
restTemplate.postForObject(  
    // code to post RegistrationInfo object);
```

Client

serialization

Data to Server

```
@PostMapping("/register")  
public int registerUser(@RequestBody RegisterDto regInfo) {  
    // create user, return created use id  
}
```

deserialization

```
public class RegisterDto {  
  
    private int userId;  
    @JsonProperty("userName")  
    private String username;  
    private String password;  
  
    // getters omitted  
  
    public void setUserId(int userId) {  
        this.userId = userId;  
    }  
  
    public void setUsername(String username) {  
        this.username = username;  
    }  
  
    public void setPassword(String password) {  
        this.password = password;  
    }  
}
```

Deserializtion Process

The `@JsonProperty` annotation says “when you see `userName` in the JSON, it means `username` in this class”

```
{
  "userId": 0,
  "userName": "judyj",
  "password": "pswd"
}
```

Using standard setter notation, setters are called based on property name (i.e. `userId` calls `setUserId`)

Behind the scenes (what Spring is doing):

- `new RegisterDto()`
- `setUserId(0)`
- `setUsername("judyj")`
- `setPassword("p`swd")`

```
public class RegisterDto {

    private int userId;
    @JsonProperty("userName")
    private String username;
    private String password;

    // getters omitted

    public void setUserId(int userId) {
        this.userId = userId;
    }

    public void setUsername(String username) {
        this.username = username;
    }

    public void setPassword(String password) {
        this.password = password;
    }
}
```

Note that `userName` in the JSON would map to `setUserName`, in the Java class, which does not exist. Which would mean that the `username` property would **not** get set.

`@JsonProperty` resolves the mismatch
